

Computer Reboot Cycling

Heat can cause a computer to reboot. A faulty fan or seized fan may not be cooling as it should. Also, dust bunnies can clog the fan. As soon as the CPU heats up, it will reboot. Try this.

1. Shutdown the computer and allow it to cool for about 10 minutes.
2. Remove the cover on the CPU cover.
3. Remove 'dust bunnies' using a can of compressed air blow out the dust.
4. Power up the CPU. If it doesn't reboot now the problem may well be the computer fan or the fan on the processor unit, if there is one.
